Problem Understanding

- The program reads an integer n from input.
- For all non-negative integers less than n, it prints the square of each number.
- Example: If n = 3, the numbers are 0, 1, 2 → squares are 0, 1, 4.

Key Concepts Practiced

1. **Input Handling**
    - n = int(input()) → Reads a single integer from standard input.
2. **Iteration with range()**
    - for i in range(n): → Loops from 0 up to n-1.
    - This ensures only non-negative integers less than n are considered.
3. **Arithmetic Operation**

- i * i → Calculates the square of each integer.
- Printed line by line using print()

Learning Outcome

- Reinforced understanding of **loops** and **range()** in Python.
- Practiced **basic arithmetic operations** inside a loop.
- Learned how to structure output line by line.
- This type of problem is typical of beginner challenges on platforms like **HackerRank**, making it a good fit for Task 3's coding practice requirement.
